

ABSTRACT
METHODS OF OPTIMISING STOCHASTIC PROCESSING
PARAMETERS IN CROP HARVESTING MACHINES

5 The flow of crop material through a harvesting machine, such as a combine, can
be described using a wide range of models, providing a relationship between the
harvester load $u(t)$, e.g. the mass flow at the inlet, and an effectiveness value $y(t)$,
e.g. the grain loss at the outlet. However, prior art models are not applicable to a
wide range of harvesting conditions or are very complicated, requiring a multitude
10 of inputs. The invention proposes to use a simple model, comprising a stochastic
parameter θ , which is continuously optimised to adjust the model to the latest
prevailing working conditions. Such parameter may be considered to constitute a
variable which characterises the instantaneously prevailing readiness of the
harvesting process. Such variable θ can be used for establishing field maps
15 showing the evolution of the harvesting operation itself. It can also be used in
automatic routines which adjust the harvester speed in order to limit the grain
losses.
